INTRODUCTION

Fistula in ano and anorectal sepsis is an established condition described in “Corpus Hippocratum” in a treatise named “ON- Fistula”. Centuries have passed but the basic principles of management of anorectal sepsis remained the same which revolves around resolution of anorectal sepsis and treatment of fistula without hampering continence. Advent of antibiotics and drainage procedures has led to adequate management of anorectal sepsis but preservation of continence still remains a challenge and efforts are on to achieve an optimal treatment which attains both leading to improvement in patient care.

PATHOPHYSIOLOGY OF ANO-RECTAL SEPSIS

Understanding the pathophysiology is one of the pivots in management of Anorectal sepsis. Widely accepted cryptoglandular theory leading to abscess formation and fistula development needs to be well understood as this is the pathology responsible for almost 90% of the perineal sepsis and anal fistulas. The obstruction of anal crypt gland with inspissated debris leads to infection in these glands, which penetrate, into the anal complex in varying degrees and suppurates follows the path of least resistance. In context to spread of infection, understanding the perineal and anal anatomy is must.

As the abscess collects in anatomical spaces where the anal gland terminates and from there on follows in the perineal spaces. It needs to be emphasized that Anorectal abscess is an acute manifestation of the crypto-glandular infection and fistula is a chronic sequelae of this infection. Almost one third of the patients who undergo drainage of the Anorectal abscess develop the anal fistula. Any recurrent perineal abscess that occurs at the same site as the previous abscesses is also a part of the continuation of the same old process and should be considered as a fistula and should be treated accordingly.

In 10% of the patients, the notable cause of the perineal sepsis is not crypto-glandular infection but it could be inflammatory bowel disease, fungal infection, tubercular infection, neoplasm or trauma. Such fistulas are classified as secondary and known to have a complex nature, requiring non-standard methods of management. There is a need to understand this because their management and outcomes differ in crypto glandular diseases and non crypto-glandular diseases.

CLASSIFICATION OF FISTULA IN ANO

Classification of fistula in ano is of immense importance as it gives accurate description of the anatomy of the course of the fistulous tract which is helpful to a surgeon in planning the operative cure of the disease. They are usually classified based on relation to the anal sphincter complex. Milligan & Morgan in 1934 classified the fistulas into high fistulas-those in which the internal opening lies above the anorectal ring and low fistulas-those in which the internal opening lies below the anorectal ring. It was a simple classification but was abandoned as the tract information was not forth coming, leading to recurrences. Park classified the fistulas into sub-mucosal, intersphincteric, supra-sphincteric and extra-sphincteric. These terms are quite informative in relation to the sphincter apparatus. The submucosal fistula is not involving any sphincter and is simplest to manage. Intersphincteric fistula traverses through the internal sphincter and are the largest category of the fistulas. Trans sphincteric fistulas pass through both the internal and external sphincters and are further subdivided into low and high depending on the part of the external sphincter muscle. The low fistulas involve only the outer part of the external sphincter while high fistulas involve greater part of the external sphincter. Incontinence would be a complication of this group. Supra sphincteric fistula typically arise at the dentate line internally, cross above the internal sphincter but below the puborectalis and exit on to the peritoneal site. Extra sphincteric fistula are rare and do not involve the sphincter complex. They arise from above the dentate line into the ischio-rectal fossa. These are non cryptogenic in nature and have different management strategies. The drawback of this classification is that it is clinically very difficult to classify them and so the need for classification oriented investigations in form of trans rectal ultrasound or Magnetic resonance imaging of perineum.

INVESTIGATIONS IN FISTULA IN ANO

Investigations in fistula in ano are aimed at formulating a surgical strategy. Digital rectal examination is an important milestone in the assessment of fistulas in ano as localization of internal or primary opening is a must in planning any treatment strategy. The primary
Management of Anorectal Fistula

**Medical Management**

Medical management is often recommended in patients suffering from inflammatory bowel disease. Even asymptomatic fistulas can be placed under observation after initial drainage of the suppurative and antibiotic treatment. Specific medical treatment of Crohn’s disease and tuberculosis needs to be started after histopathological conformation by biopsy in both these conditions is mandatory and this histopathology helps in excluding neoplastic diseases.

**Setons**

Setons are other optional treatment for high trans-sphincteric and anterior trans-sphincteric fistulae in women and they should be used in patients with high probability of incontinence. The materials used for Setons are non absorbable sutures like prolene, penrose drains, rubber bands, vessel loops and silastic catheters. Amecidated ayurveda thread called kshar sutra was the earliest known seton described by Sushruta which was linen thread soaked in kshar, an alkaline chemical from plant extracts that has a slight tissue cutting property. Two types of setons are used formanagement of fistulas. The cutting setons which incise through the tissue and the non-cutting setons which facilitate the drainage of the tract. It takes 3 weeks to 1 year to cut through the tissue. Use of surgical gloves as a cutting seton was an innovation to prevent repeated change of setons and healing is reported from one month to one year. Non cutting setons were mainly used in chronic sepsis and chronic diseases like HIV positive patients. Recently Setons have been used in combination with fistulotomy as staged procedure. Multiple setons are placed through tracts after the basic tracts are removed. Incontinence still continues to complicate the treatment, though they are projected as sphincter saving procedures and the reasons for this could be hard gutter shaped scars, loss of anal canal sensations.

The use of setons in modern day practices is restricted to complex and hard to treat fistula which are prone for recurrence. In an unpublished comparative study carried out by us Medicated Seton (Ksharsutra) was compared with Fistulectomy in patients of low fistula in ano. Of 63 patients, 56 males and 7 females, with a mean age 38.40 yrs Fistulectomy group had 31 patients & Medicated Seton (Ksharsutra) group had 32 patients, were well matched for demographic data and fistula characteristics defined on MRI scan. The mean healing duration was similar in both groups. Recurrence was seen in 14% of the patients.

**Surgical Management Fistulotomy**

This is the standard treatment for low simple anal fistulas, submucosal and low inter-sphincteric fistulas. The indications are low cryptoglandular fistulas, low chronic fistulas, simple fistulas where 30-50% of the tracts pass through the sphincter, which is not anterior in female, single tract, non recurrent, continent, non chronic. Fistulotomy is usually a single stage procedure but in complex procedures it can be used as a staged procedure with adjuvant seton or glue therapy. The incontinence rate varies from 0-40% in low inter-sphincteric fistulas.

**Radiation Ablation** of tract is another improvement in techniques of fistulectomy. It is known to have decreased gas continence as radiation therapy ablation causes minimal damage to surrounding tissue. Ultrasound dissection of the fistulous tract is a future advancement. The recurrence rate of fistulotomy is 7-16% after 2 yrs follow up. This recurrence rate increases to 40% after 6 yrs. Fistulotomy forms an important part of fistula management despite the high rate of incontinence and recurrence.

**Fistulectomy**

Studies have shown that Fistulectomy does not offer any additional advantage over the Fistulotomy procedure.

**Newer Modalities**

1. **Fibrin Glue** - it is a mixture of fibrinogen, thrombin and calcium ions which when combined form a soluble clot due to cleavage of fibrinogen to fibrin. This clot seals the fistula tract in 30-60 seconds. Between days 7 and 14 the tract is replaced by synthesized collagen. Success rates of this procedure ranges from 31-85%.

2. **Fibrin Plug** - since its first introduction in 2006 by Robb & colleagues, it has achieved wide range of success from 14% to 87%. The plug is made up of lyophilized porcine small intestinal submucosa shaped in a conical fashion which increases the mechanical stability thus avoiding dislodgement during straining.

3. **Adipose Derived Stem Cells** have been used in the treatment of complex anal fistulas. On comparison with fibrin glue, the results have been promising with a recurrence rate of 17% at one year follow up.

4. **Mucosal Advancement Flap** - this a sphincter sparing procedure where endorectal/endoanal flaps are advanced to close the internal ring with or without closure of the tract. Healing rate varies from 77-100%. Recurrence rate was noted to be 23%.

5. **LIFT procedure** - it is ligation of the inter sphincteric fistula tract first described by Rojanasakul in Thailand. The reported success rate of the procedure was 58%.

**Summary**

The management of anorectal sepsis and fistula in ano needs complete knowledge of perineal anatomy and pathophysiology. The sphincter complex is the nodal factor and the type of pathology is important. The first line management should be sphincter saving where sphincter division is avoided. Aggressive surgical approach is only considered.
Check-list

MANUSCRIPT SUBMISSION FOR JIMSA

(i) Copyright statement/declaration (not submitted or published elsewhere) signed by all the authors.
(ii) Three hard copies of manuscript with illustrations attached to each; must send an electronic copy of text with photographs loaded on CD.
(iii) Title page: Title of Manuscript, Name(s) and affiliation of author(s); Institution(s) and city(ies) address of corresponding author.
(iv) The text of the article should contain Abstract highlighting objectives, methods, results, conclusions.
(v) Original Article (double-spaced on A-4 size paper): Should contain introduction material & methods, results, discussion; Indian Literature must be referred.
(vi) Update/Review: Therapy update should have appropriate headings, with reference numbers in the text; Indian Literature cited, wherever available.
(vii) References: maximum number of references for update-30, original-20, Case reports-6:8.
(viii) Each table on separate sheet; maximum number-4 in original article; 6 in update.
(ix) Photographs/figures in envelope, each marked figure number on reverse with legends on separate sheet, numbers not to exceed 4 in original, 2 in case report.
(x) Statement signed by all authors regarding adherence to Standard ethical guidelines prescribed by ICMR 2000.

Guidelines for the Award

1. No. of Grants-Two (2).
2. Original research work by a young researcher (age < 45 years) for presentation at IMSACON every alternate year for travel within the country.
3. Research work should clearly project the objectives, selection of material, methodology adopted, results analysis with statistics, discussion and conclusions. A summary in 350 words highlighting why the paper should be considered for the award, must be enclosed.
4. Travel Grant not exceeding Rs.8000/- per awardee, to cover the travel expenses with in the country.
5. The abstract of the paper should be sent to the Chairman, Scientific Committee, IMSACON (for acceptance and presentation at the conference) bearing a label “JIMSA Travel Grant.” Only accepted papers will be judged for “Travel Grant”.
6. In case the applicant is in Governement job, he should enclose a letter from the Head of Department/Institution certifying that he is not being supported by any other agency.
7. Selected candidates will be required to submit full manuscript (3 copies along with one CD) prepared as per the format of JIMSA (Check list above) to be sent to Editor, JIMSA at office address for the publication in JIMSA. The article will be accepted for publication in JIMSA only after the proper peer review by the referees.

P. D. Gulati, Editor, JIMSA
